CLINICAL

Questions:

- What are the mechanisms of action of SARS-CoV-2?
- What are the cellular and humoral host responses against SARS-CoV-2 infection?
- What are the clinical features of COVID-19 in adults and children?
- Is there multiple-organ damages associated to COVID-19?
- What are the long term effects of Covid-19?

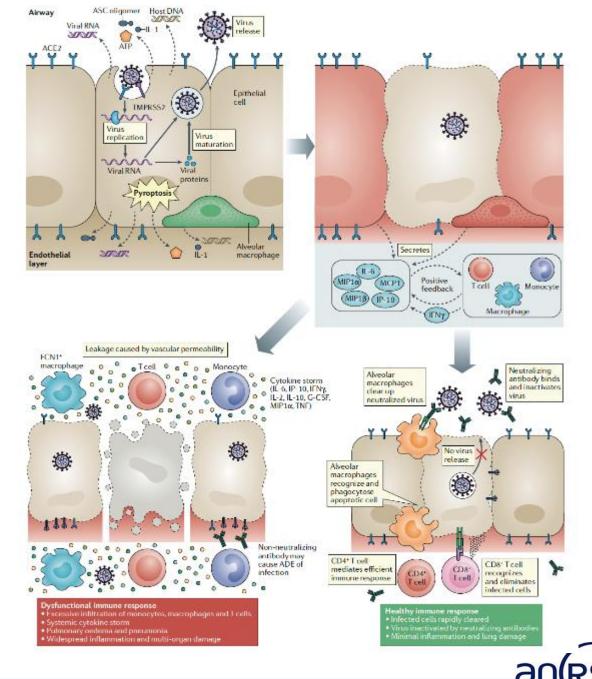

MALADIES INFECTIEUSES ÉMERGENTES

Physiopathology

- Binding to host cell through ACE2 receptor by spike (S) protein
 - Lung, Kidney, Heart, Brain ...
- Fusion of the viral envelope with cellular membrane (TMPRSS2)
- Virus hijacks the cell machinery
- Host cell → pyroptosis and release damage-associated molecular
 - ATP, nucleic acid, ASC oligomer ...
- Inflammatory response
 - o Pro-inflammatory cytokines & chemokines: IL-6, IP-10, MCP1 ...
- Attract other cells (monocytes, macrophage, T cells ...)
 - o Pro-inflammatory feedback loop
 - Eliminates the infected cells before the virus spreads

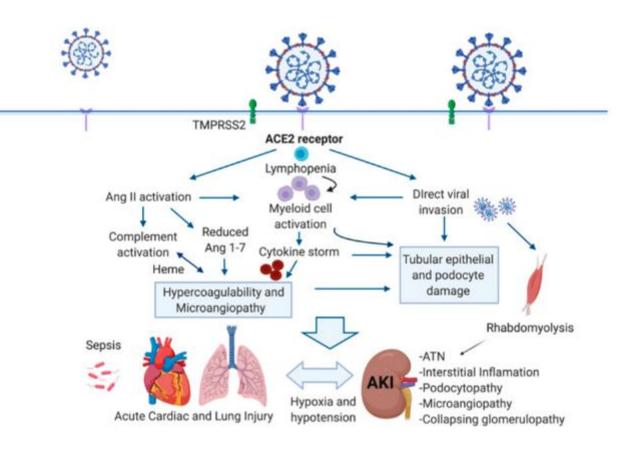

BUT sometimes (10 to 15 days after symptom onset)

- Accumulation of immune cells
 - Hyper-inflammatory response
 - Lung damage and multi-organ damage

Physiopathology

- SARS-CoV-2 targets ACE2 receptor and infected cells via « priming »
 - o Renin- Angiotensin system dysregulation
 - Activation of innate and adaptative immune pathways
 - Cytokine storm
 - coagulation pathway → hypercoagulation
- Multi-organ damage
 - o Kidney, heart, lungs, vessel, immune system

Auto-antibodies & type I IFN & COVID-19

Neutralizing auto-Abs against type I IFN could lead to life-threatening COVID-19 pneumoniae?

987 patients hospitalized for life-threatening COVID-19

663 patients asymptomatic or mildly symptomatic (COVID-19)

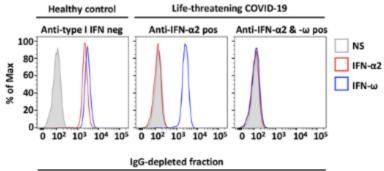

1227 healthy controls

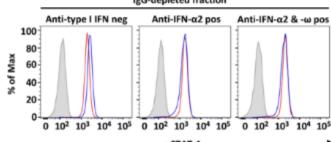

Auto-antibodies against IFN- α 2 and/or IFN- ω ?

 135 of 987 critically ill patients had IgG auto-Abs against at least one type I IFN.

Auto-Abs neutralize IFN- α 2 and/or IFN- ω in vitro?

- 101 of 987 life-threatening COVID-19 had neutralizing IgG auto-Abs against at least one type I IFN:
 - 51% against IFN-α2 and IFN-ω,
 - 36% against IFN-α2 only,
 - 13% against IFN-ω only.
- Auto-Abs detected in only 4 of 1227 controls and none of 663 asymptomatic or mild-symptomatic patients.

FACS plots depicting IFN- α 2- or IFN- ω -induced pSTAT1 in the presence of 10% healthy control or anti-IFN- α 2/ ω - auto-Abscontaining patient plasma (top panel) or an IgG-depleted plasma fraction (bottom panel).

IgG depletion from patients with auto-Abs restored normal pSTAT1 induction after IFN- α 2 and IFN- ω stimulation.

Auto-antibodies & type I IFN & COVID-19

<u>Auto-Abs against all IFN-α subtypes</u>?

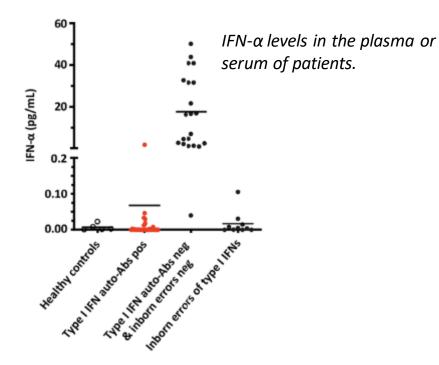

- All patients (22) with neutralizing auto-Abs against IFN- α 2 had auto-Abs against all 13 IFN- α subtypes
- Early treatment with IFN- α is unlikely to be beneficial

<u>Auto-Abs against IFN-β?</u>

- 1,9% of the patients had auto-Abs against IFN-β
- All were severe COVID-19
- Treatment with injected or nebulized IFN-β may have beneficial effects

In vitro and in vivo?

- In patients with neutralizing auto-Abs against IFN-α2, the baseline levels of type I IFN-dependent transcripts were low,
- Neutralizing in vitro & in vivo
- Suggesting a pre-existing or concomitant biological impact in vivo

- → Auto-Abs against type I IFNs are a cause of severe SARS-CoV-2 infection.
- → Provides an explanation for the major sex bias in severe COVID-19 and the increase in risk with age
- → Clinical and therapeutic implications

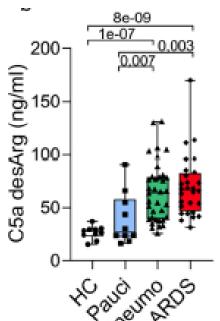

C5a-C5aR1 axis & COVID-19

C5a anaphylatoxin and its receptor C5aR1 play a key role in the initiation and maintenance of inflammatory response

Recruiting and activating neutrophils and monocytes

82 individuals: 10 healthy control, 10 paucisymptomatic COVID-19, 34 with pneumonia & 28 with ARDS due to SARS-CoV-2.

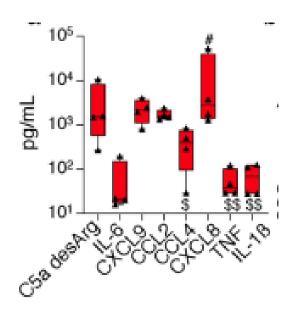

Concentration of C5a desArg in plasma

An increase in plasma C5a levels proportional to COVID-19 severity.

Increased systemic and local complement pathway activities on the peripheral blood.

C5a is detected in lung sample from COVID-19 patients

Saliva specimens could be effective in the diagnosis of COVID-19

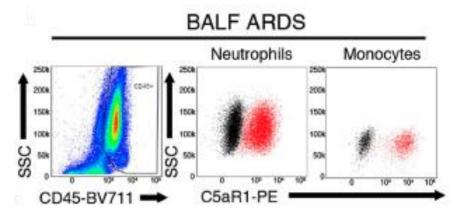

C5a-C5aR1 axis & COVID-19

C5a production leads to the chemo-attraction and activation of myeloid cells in the lung \rightarrow release of inflammatory cytokines.

Possible that the vasculitis associated with severe COVID-19 is linked to the production of C5a.

CD45⁺ immune cell infiltration in BALF C5a-R1 expression (red)

Neutrophils and monocytes in BALF expressed C5aR1.

Potential therapeutic strategy → C5a-C5aR1 axis blockade. Avdoralimab = mAb against C5aR1.

In vitro:

- inhibited C5a-induced neutrophil activation,
- Inhibited the C5a-induced migration of neutrophils.

In mice:

- Mice received an intranasal instillation of recombinant human C5a → developed ALI.
- Avdoralimab prevented albumin release in BALF
- Avdoralimab inhibited the increase in IL-6, TNF and CCL2.
- Avdoralimab inhibited ALI in mice

CR5a-C5aR1 axis blockade might be used to prevent the excessive lung inflammation and endothelialitis associated with ARDS in COVID-19 patients

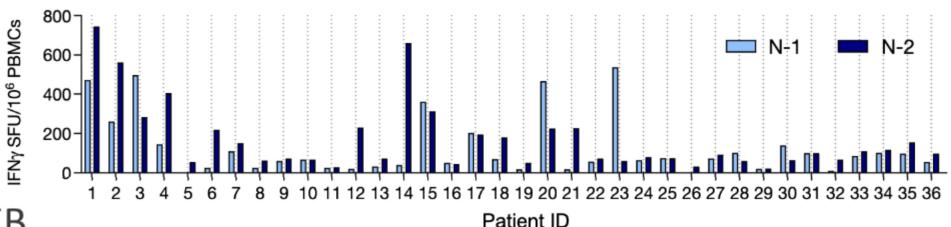

SARS-CoV-2 specific T cell immunity

SARS-CoV2 specific T cells in patients with COVID-19

- 36 individuals after recovery from mild to severe COVID-19.
- T cell response against selected structural (N) and non-structural proteins (NSP7, NSP13 & ORF1).
- Use of an unbiased method with overlapping peptides.
- Peripherical blood mononuclear cell (PBMC) of the 36 patients were stimulated for 18h with the different peptides pools.
- In 36 out of 36 individuals, found specific T cell that recognized multiple regions of the N-protein (IFNγ spot)

Unexposed

n = 37

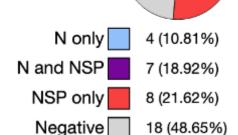

SARS-CoV-2 specific T cell immunity

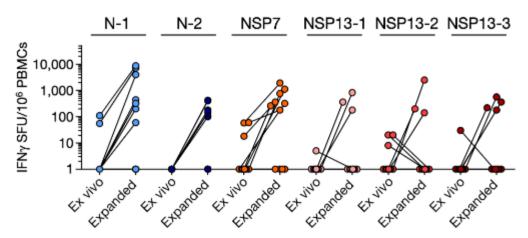

SARS-CoV2 specific T cells in unexposed donors

- 37 donors: not exposed to SARS-CoV and SARS-CoV-2
- Detection of SARS-CoV-2-specific IFNγ responses in 19 out of 37 unexposed donor.
- The unexposed group showed a mixed response to the N protein or to NSP7 and NSP13.
- These SARS-CoV-2-reactive cells from unexposed donors had the capacity to expand after stimulation with SARS-CoV-2-specific peptides.

→ Infection with betacoronaviruses induces multi-specific and long lasting T cell immunity against the structural N protein.

Before and after expansion (SARS-CoV-2 peptides)

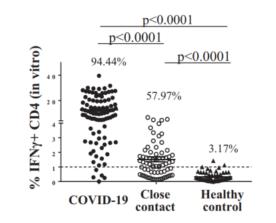

SARS-CoV-2 specific T cell immunity

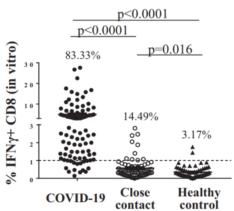

Samples: peripheral blood mononuclear cells (PBMCs) from:

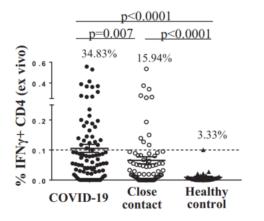

- 90 COVID-19 patients, collected 48-86 days after disease onset
- 69 close contacts (NAT-neg, SARS-CoV-2 IgG/IgM-neg), collected 48-86 days after contact with COVID-19 patient
- 63 healthy donors, collected in September 2019

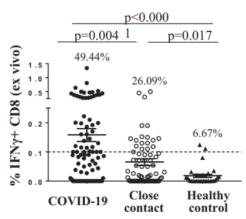

in vitro: PBMC expansion and 10 day-stimulation with peptide pool targeting spike, membrane and envelope glycoproteins, nucleocapsid, RNA polymerase ORF1ab *ex vivo*: PBMCs stimulated overnight with peptide pool

- > 94.44% CD4+ and 83.33% CD8+ SARS-CoV-2 specific T cells of COVID-19 patients, and 57.97% CD4+ and 14.49 CD8+ of close contacts underwent in vitro expansion.
- > Healthy donors showed minimal cross-reactive T cells from other coronaviruses, but at a significantly lower frequency than T cell immunity of close contacts.
- > ex vivo data corroborated these results and showed significant differences between T cell memory pools and INFγ production of patients and close contacts.
- Memory T cell immunity is detectable in both symptomatic and asymptomatic COVID-19 patients, with no significant difference in T cell pool size and qualities.
- > Following *in vitro* expansion, virus-specific memory CD4+ T cell pool correlated with titers of IgG against S RBD and N protein.

INFy expressing T cell exantion upon in vitro and ex vivo PBMC stimulation with peptide pools encompassing viral epitopes

SARS-CoV-2-specific memory T-cell immunity was observed in COVID-19 patients and close contacts at D48-86

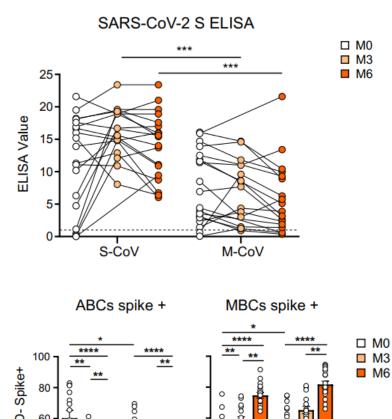

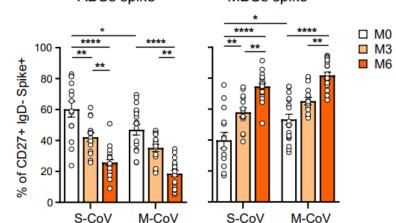

SARS-CoV-2 specific B cell immunity

21 Severe (S)-Cov vs 18 Mild (M)-Cov patients assessed at 3 and 6 months

- S-specific IgG are stable with time in both cohorts, but appear significantly higher in S-CoV patients
- At 6 months, B cells **mostly resided in the memory B cell (MBC) compartment** in both cohorts, while S-specific antigen secreting cells were marginally detectable. S-specific MBCs were at higher frequencies S-CoV patients, but present also in M-CoVs.
- > In both S-CoVs and M-CoVs, the proportion of S-specific activated B cells (ABCs) steadily decreased over time, along with an increase of S-specific classical, resting MBCs.

A robust and stable S-specific MBC population is induced in both M- and S-CoV patients

SARS-CoV-2 specific B cell immunity

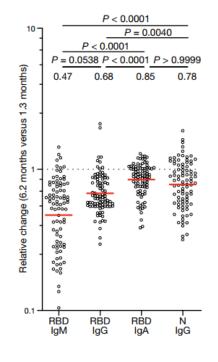

87 participants assessed at 1.3 and 6.2 months after infection

Antibody response:

- Anti-RBD and ELISA anti-N antibodies in plasma decreased significantly between
 1.3 and 6.2 months.
- IgM showed the greatest decrease in anti-RBD reactivity (53%), followed by IgG (32%); anti-RBD IgA decreased by only 15% and anti-N IgG levels by 22%.
- Individuals with persistent post-acute symptoms had significantly higher levels of anti-RBD IgG and anti-N total antibody.
- Neutralising activity: NT50 was 401 and 78 at 1.3 and 6.2 months, respectively →
 5-fold decrease. Neutralizing activity was directly correlated with IgG anti-RBD.

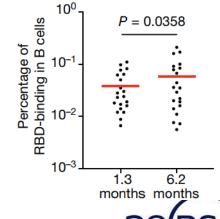

B cell response:

- The % of RBD-binding memory B cells increased marginally between 1.3 and 6.2 months (n=21).
- although the magnitude of the RBD-specific memory B cell compartment is conserved between 1.3 and 6.2 months after infection, there is extensive clonal turnover and antibody sequence evolution, consistent with prolonged germinal centre reactions.

Relative change in plasma antibody levels

Immunological assessment

Cohort study of 178 confirmed SARS-CoV-2 infection

Asymptomatic infection = 20,8% (37/178 patients)

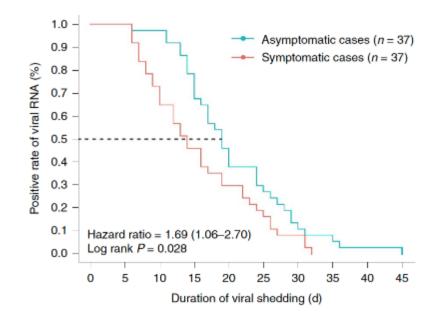

37 asymptomatic matched with 37 mild symptomatic patients

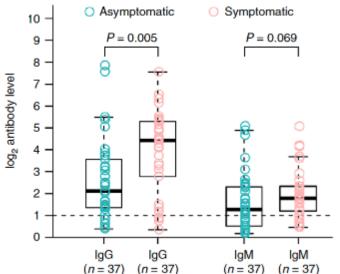

Viral shedding:

- Initial Ct value were similar in the two groups
- Asymptomatic group had a significantly longer duration of viral shedding (19 days versus 14 days; p=0.028)

IgG and IgM, 3 to 4 weeks after exposure (acute phase):

- IgG positivity rates similar between the two groups (81 and 84% of asymptomatic and symptomatic, respectively)
- IgG levels in the asymptomatic group (median S/CO, 3.4; IQR, 1.6–10.7) were lower than the symptomatic group (median S/CO, 20.5; IQR, 5.8–38.2; p = 0.005)
- IgM levels were similar in the two groups (62 and 78% of positivity of asymptomatic and symptomatic, respectively)

Immunological assessment

IgG and IgM, 8 weeks after exposure (convalescent phase)

- A decline of IgG is observed among >90% of patients
- 40% and 13% of asymptomatic individuals IgG+ at the acute phase became seronegative

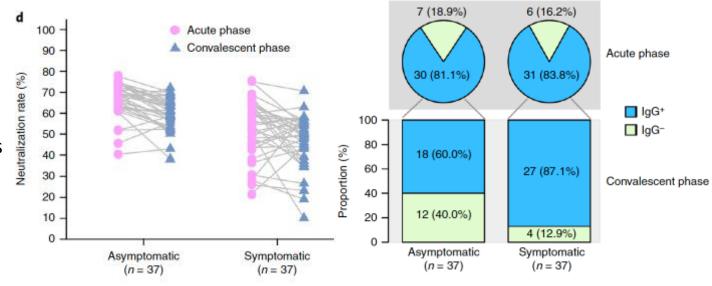

Similar observations were made for neutralizing antibodies

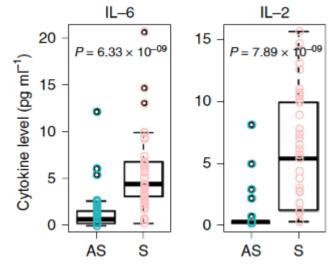

Asymptomatic patients had a reduced inflammatory response with lower concentration of circulating cytokines and chemokines

The relatively low seroprevalence and its decrease within 2-3 months after infection highlights the potential limits of serology for diagnostic and the need of timely serosurvey

- → Viral RNA shedding does not equate viral infectivity (not assessed in this study)
- →Serological observations may depend in part on the commercial assay used

Antibody response to SARS-CoV-2

Cohort of 149 cases and contacts: 111 with SAR-CoV-2 PCR positive + 46 close contacts.

Free of symptoms at least 14 days at the time of sample collection.

- → Convalescent plasma samples
- Binding to SARS-CoV-2 RBD and trimetric S protein?

IgG response: 78% showed anti-RBD and 70% anti-S

IgM response: 15% showed anti-RBD and 34% anti-S

Anti-RBD IgG levels → moderately correlated with age and severity

Neutralizing activities? → the half-maximal neutralizing titer (NT₅₀)

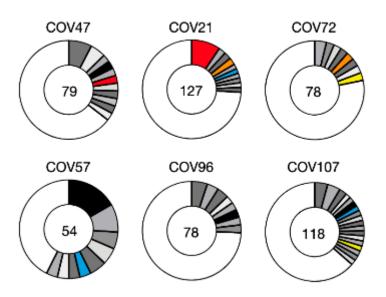

Generally low: NT_{50} <50 in 33% of samples and < 1000 in 79%

Nature of the antibodies elicited by SARS-CoV-2 infection?

Expanded clones of viral antigen-binding B cells in all tested individuals convalescent after COVID-19.

95% of the antibodies tested bound to SARS-CoV-2 RBD with an average EC_{50} of 6,9 ng/ml

The distribution of antibody sequences from six individuals
The number in the inner circle indicates the number of
sequences analyzed for the individual denoted above the
circle. White indicates sequences isolated only once, and
grey or colored pie slices are proportional to the number of
clonally related sequences.

Antibody response to SARS-CoV-2

Do monoclonal antibodies have neutralizing activity?

Among 89 RBD-binding antibodies tested, we found 52 that neutralized SARS-CoV-2 pseudovirus with IC50 values ranging from 3 to 709 ng/ml.

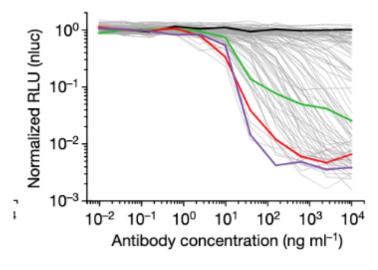

Potent neutralizing antibodies found irrespective of the NT₅₀ values.

→ Even individuals with modest plasma neutralizing activity have rare IgG memory B cells that produce potent SARS-CoV-2-neutralizing antibodies.

Plasma neutralizing activity is low in most convalescent individuals Recurrent anti-SARS-CoV-2 RBD antibodies with potent neutralizing activity can be found in all individuals.

A vaccine designed to elicit such antibodies could be broadly effective.

The normalized relative luminescence values for cell lysates of 293TACE2 cells 48 h after infection with SARS-CoV-2 pseudovirus in the presence of increasing concentrations of monoclonal antibodies.

Neutralizing antibodies to SARS-CoV-2 infection

Understanding the protective effects of the immune response ⇔ neutralizing effects of SARS-CoV-2 antibodies

Mont Sinai Health System screen individuals for antibodies to SARS-CoV-2

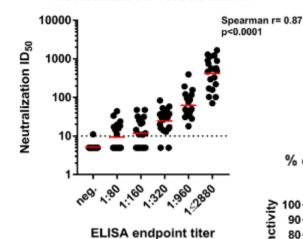

- 72,401 individuals screening: 30,082 positive & 42,319 negative
- Vast majority of positive individuals have moderate-to-high titer of antispike antibodies.
- Seroconverters = titer of 1:320 or higher

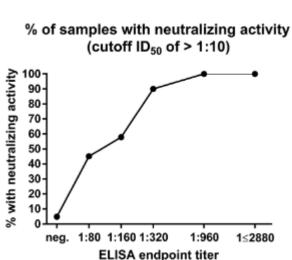

<u>Neutralizing effects</u> → quantitative microneutralization assay

- 120 samples of known ELISA titers ranging from negative to ≥1:2880
- Neutralization titers significantly correlated with spike-binding titers
- 90% of seroconverters make detectible neutralizing antibody responses

Neutralizing activity of serum samples in relation to ELISA titers.

Neutralization versus ELISA

Neutralizing antibodies to SARS-CoV-2 infection

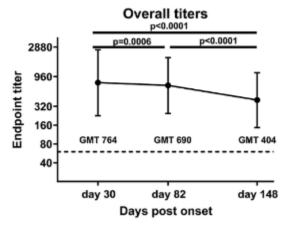

Longevity of the antibody response:

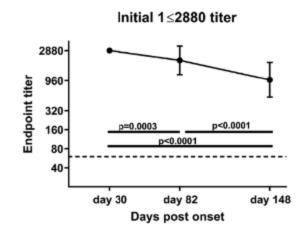

- Slow decline in titer over time
- Initial increase in individuals with a initial titer of 1:320 or lower
- Titer remains relatively stable for several months after infection (\sim 5)
- Good correlation between neutralization and ELISA titers on day 148

Correlation between specific level of antibody and risk of (re)infection?

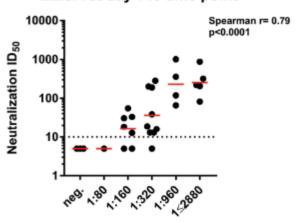

- Still unclear for infection with SARS-CoV-2 in humans
- → Individuals who have recovered from mild COVID-19 experience relatively robust antibody response to the spike
- → Correlation between spike-binding titers and neutralization titers
- → Stable antibody titers over 3 months and modest declines at the 5-month time point

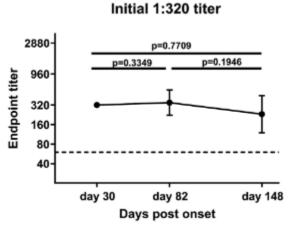

Antibody titer stability over time

Correlation of neutralization versus ELISA at day 148 time point

ELISA endpoint titer

Cannot provide conclusive evidence: do this antibody responses protect from reinfection?

Long term humoral response against SARS-CoV-2

Anti-SARS-CoV-2 antibody persistance in COVID-19 patients after 6 months (1/3)

- > 532/9542 individuals tested positive for pan-immunoglobulins (Wuhan).
 - Seroprevalence adjusted for sex, age group and district: 6.92%
 - 1st follow-up at 2 months, 2nd at 6 months

	IgG	IgA	IgM	Neutralising Ab
Baseline (n=532)	532 (100%)	84 (15.8%)	69 (13.0%)	212 (39.8%)
1st follow-up (n=363)	354 (97.5%)	36 (9.9%)	14 (3.9%)	162 (44.6%)
2 nd follow-up (n=454)	413 (91.0%)	16 (3.5%)	7 (1.5%)	187 (41.2%)

➤ **Titers** of pan-Ig, IgG , IgM and IgA continuously decreased significantly accross the study period

Seroconversion rates of neutralising Ab at baseline and second follow-up:

	Baseline	2 nd follow-up	P value
Confirmed (n=27)	18 (66·7%)	16 (59·3%)	0.54
Symptomatic (n=55)	35 (63·6%)	35 (63·6%)	1.000
Asymptomatic (n=253)	88 (34·8%)	103 (40·7%)	0.38
Total (n=335)	141 (42·1%)	154 (46·0%)	0.55

➤ The proportion of patients positive for IgM, IgA and IgG decreased in all three subgroubs

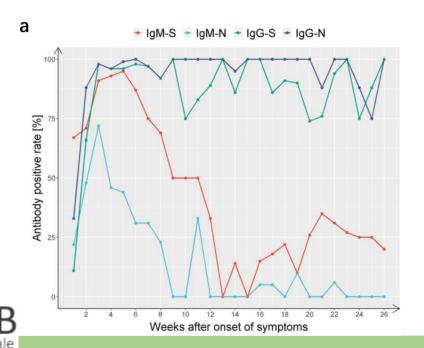

Long term humoral response against SARS-CoV-2

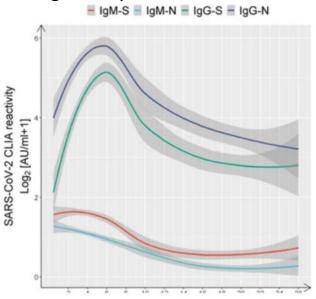

Anti-SARS-CoV-2 antibody persistance in COVID-19 patients after 6 months (2/3)

IgM and IgG responses against RBD of S and N proteins over 26 weeks (W) in 349 symptomatic COVID-19 patients, Wuhan

- Antibody positivity rate:
 - W1: IgM-S (67%) > IgG-N (33%) > IgM-N (22%) > IgG-S (11%)
 - IgM-S peaked (95%) at W5, then decreased below 35% after W13
 - IgM-N reached 72% at W3, then became undetectable at W10-12
 - IgG-N and IgG-S reached high positivity rate at W2 and 3 respectively, and remained high over the study period

- Antibody titers:
 - IgM-N and IgM-S peaked at W3 and 4, and fell below cutoff value at W9 and 12
 - IgG-N and IgG-S peaked at W4 and 5, respectively, underwent a contraction phase (W6-14) and then stabilised and high level over the study period
- IgG-RBD-S titer was highly positively correlated with neutralising activity

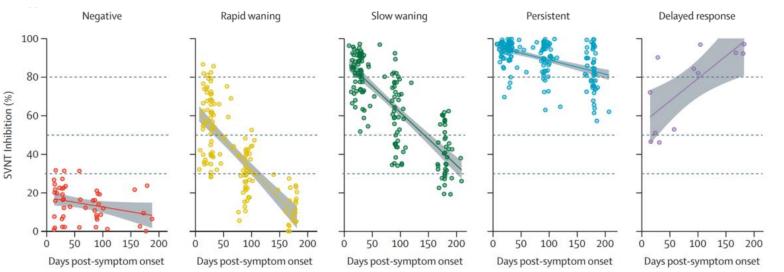

Long term humoral response against SARS-CoV-2

Anti-SARS-CoV-2 antibody persistance in COVID-19 patients after 6 months (3/3)

Neutralising antibodies (nAB) in 164 COVID-19 patients, Singapore, 180 days post symptom onset

- 5 patterns of nAb dynamics observed:
 - Negative did not reach 30% inhibition level): 12%
 - Rapid waning positive early on but seroverting: 27%
 - Slow waning remain nAb-positive over study period: 29%
 - Persistent minimal nAb decay 32%
 - Delayed response increase of nAb ≥90 days postsymptom onset: 2%

- Persistent group showed higher levels of pro-inflammatory cytokines (IFN-γ, IL-12p70, and IL-17A) and chemokine (IP-10), and growth factors as compared with other groups at 180 days
- All patients maintained specific (NP, M, S) T-cell response at 180 days
- Disease severity independently was associated with persistent antibody levels

Linear regression model of each grouping for neutralising antibody level. Dashed lines represents 30%, 50%, and 80% of sVNT percentage inhibition.

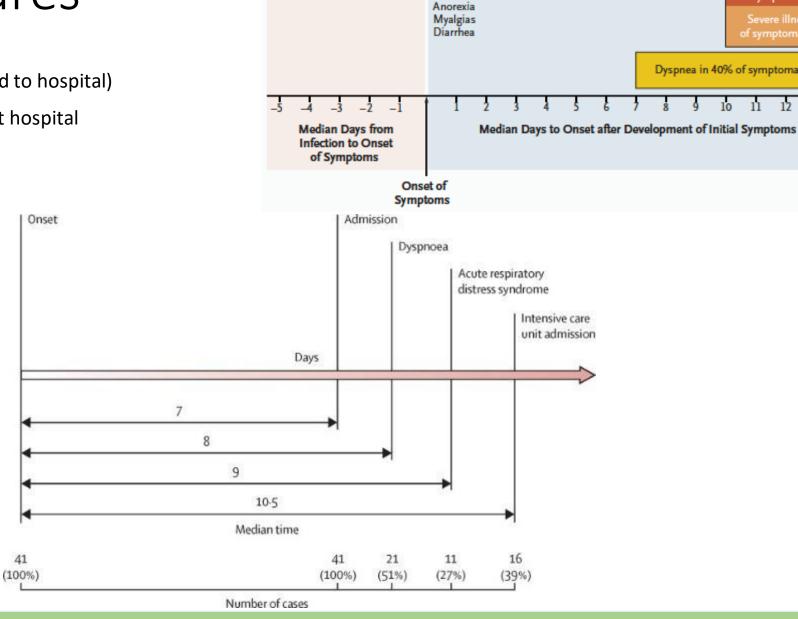

Clinical features

Median time (41 patients admitted to hospital)

- From onset of symptoms to first hospital admission
 - o 7 days [4,0–8,0]
- From illness onset to dyspnea
 - **8 days** [5,0–13,0]
- To ARDS
 - o 9 days [8,0–14,0]
- To ICU admission
 - 10,5 days
- To mechanical ventilation
 - o **10,5** days [7,0–14,0]

Incubation Period

Fever

Cough

Fatigue

Critical illness in 5%

of symptomatic patients

of symptomatic patients

Dyspnea in 40% of symptomatic patients

Clinical features

China, 1 590 hospitalized patients (13,4% of all cases reported in China)

Age (median): 48,9 ± 16,3 years

Male: 904 (57,3 %)

Comorbidities

• Hypertension: 16,9 %

• Diabetes: 8,2 %

• CHD: 3,7 %

• Cerebrovascular disease: 1,9 %

• COPD: 1,5 %

• Chronic kidney disease: 1,3 %

Malignancy: 1,1 %

Symptoms

• Fever: 88 %

• Cough: >70 %

• Fatigue: 42,8 %

• Shortness of breath: 20,8 %

Myalgia/arthralgia: 17,5 %

Abnormal chest CT: 1130 (71,1 %)

• Pharyngalgia: 14,7 %

• Headache: 15,4 %

• Chill: 12,2 %

Nausea/vomiting: 5,8 %

• Diarrhea: 4,2 %

Outcomes

Critical illness: 131 (8,24 %)

• ICU admission: 99 (6,23 %)

Mechanical ventilation: 50 (3,1 %)

Case fatality rate: 50 (3,1 %)

Organ damage

An invader's impact

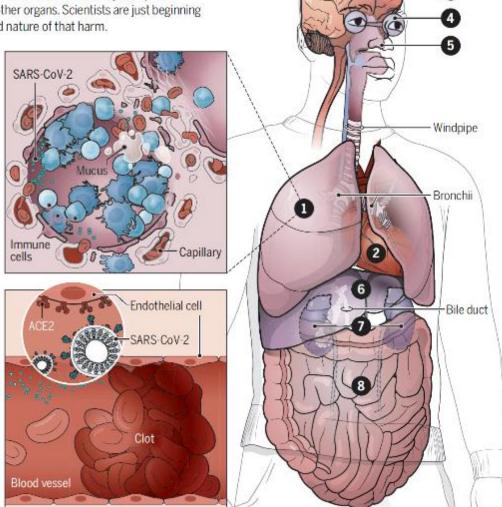

In serious cases, SARS-CoV-2 lands in the lungs and can do deep damage there. But the virus, or the body's response to it, can injure many other organs. Scientists are just beginning to probe the scope and nature of that harm.

1 Lungs

A cross section shows immune cells crowding an inflamed alveolus, or air sac, whose walls break down during attack by the virus, diminishing oxygen uptake. Patients cough, fevers rise, and breathing becomes labored.

2 Heart and blood vessels

The virus (teal) enters cells, likely including those lining blood vessels, by binding to angiotensin-converting enzyme 2 (ACE2) receptors on the cell surface. Infection can also promote blood clots, heart attacks, and cardiac inflammation.

3 Brain

Some COVID-19 patients have strokes, seizures, confusion, and brain inflammation. Doctors are trying to understand which are directly caused by the virus.

4 Eyes

Conjunctivitis, inflammation of the membrane that lines the front of the eye and inner eyelid, is more common in the sickest patients.

5 Nose

Some patients lose their sense of smell. Scientists speculate that the virus may move up the nose's nerve endings and damage cells.

6 Liver

Up to half of hospitalized patients have enzyme levels that signal a struggling liver. An immune system in overdrive and drugs given to fight the virus may be causing the damage.

7 Kidneys

Kidney damage is common in severe cases and makes death more likely. The virus may attack the kidneys directly, or kidney failure may be part of whole-body events like plummeting blood pressure.

8 Intestines

Patient reports and biopsy data suggest the virus can infect the lower gastrointestinal tract, which is rich in ACE2 receptors. Some 20% or more of patients have diarrhea.

Radiology

Monocentric – from 16 January to 17 February 90 patients - Median follow up: 18 days [5 – 43] <u>CT interpretation</u> (366 CT scan)

- → Each lung divided into 3 zones
- \rightarrow Overall CT score (max = 24)

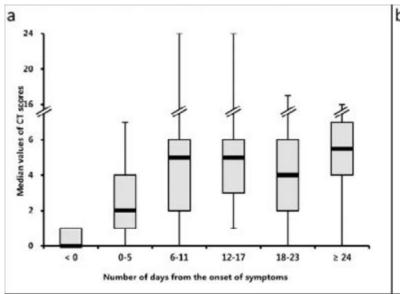

<u>Results</u>

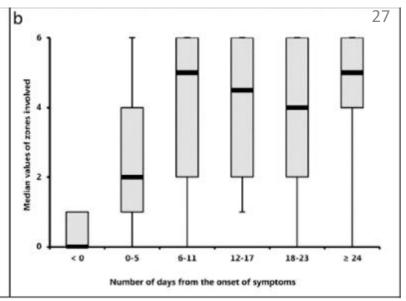

- Increase median values of CT score with time
- Peak levels of lung involvement: 6-11d from symptom onset
- Ground glass opacity (GGO) is the most common finding
- More diverse manifestations around 6-11d and after
- Sensitivity of CT for SARS-CoV-2 increase over time
- At discharge: 64% still had abnormalities

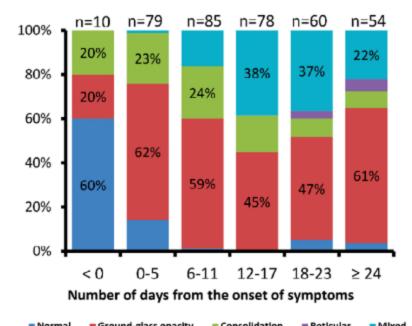

<u>Limitations</u>: No subgroup analysis (mild and severe)

→ Rapid extension and specific pattern of evolution

MALADIES INFECTIEUSES ÉMERGENTE

Radiology

Ground glass opacity in a 35-year-old woman with COVID-19 pneumonia

TIME

Heart & COVID-19

Acute myocarditis

- 7 17% of hospitalized patients
- 22 31% patients admitted in ICU
- 7% of COVID-19 related deaths

Acute myocardial infarction

- Viral illness → increase the risk
- Inflammation + hypercoagulability → increased risk

Acute heart failure

- 20-25% of patients in their initial presentation
- Increased risk of mortality
- New cardiomyopathy or exacerbation?

Dysrhythmias

- 17% of hospitalized and 44% of ICU patients
- Hypoxia, inflammatory, abnormal metabolism

Venous thromboembolic event

- Increased risk
- Inflammation, organ dysfunction, abnormal coagulation
- 16-17% of pulmonary embolism

ECG and echocardiographic abnormalities

Correlated with worse outcomes

Risks

Complications

Older Age

Comorbidities - CVD, lung, renal, diabetes

Systemic Inflammation

Coagulation Abnormalities

Severe Illness and Multiorgan Dysfunction

Immobility

Myocardial Injury and Myocarditis

Acute Myocardial Infarction

Heart Failure and Cardiomyopathy

Arrhythmias

Shock and Cardiac Arrest

Venous Thromboembolic Event

Kidney & COVID-19

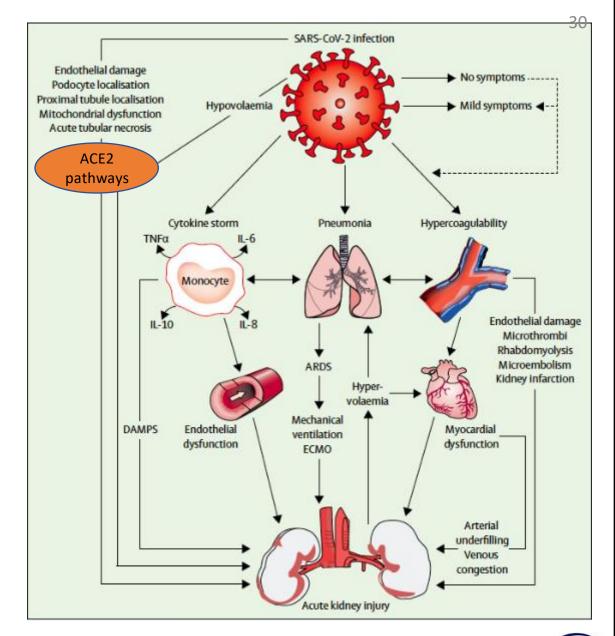

Introduction

- > 40% cases of COVID-19 have abnormal proteinuria at hospital admission
- Patients admitted to ICU with COVID-19:
 - 20 to 40% have an AKI
 - 20% require renal replacement therapy (RRT)

<u>Pathophysiology</u> → multifactorial with predisposing factors

Management

- Implementation of KDIGO guidelines
- Restore normal volume status
- Reduce the risk of
 - Pulmonary oedema
 - Right ventricular overload
 - Congestion
- Application of lung-protective ventilation
- RRT
 - Volume overload ± refractory hypoxemia
 - Right jugular vein
 - Anticoagulation protocols: LMWH or UFH

Kidney & COVID-19

<u>Prospective cohort – 1 hospital in China – **701 patients**</u>

- Prevalence of acute kidney injury (AKI)?
- Association between markers of kidney injury and death?

Age (median): 63 years with 52,4% male

Illness onset to admission: 10 days

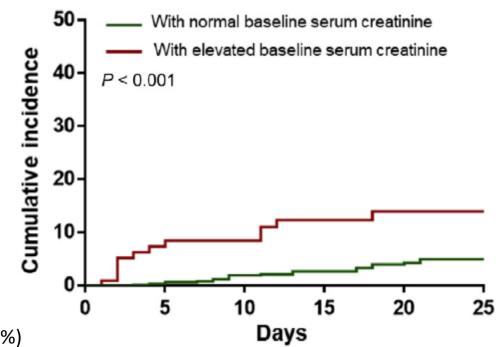

<u>Kidney injury</u> (at admission)

- Elevated serum creatinine (SC) at admission 14,4%
- Elevated BUN at admission 13,1%
- GFR<60 ml/min/1,73m² for 13,1%
- Proteinuria (43,9%) & hematuria (26,7%)

AKI and hospital death

- Prevalence of AKI: 5,1% higher in patients with elevated SC at admission(11,9%)
- In hospital death: 16,1%
 - 33,7% in patient with elevated SC at admission vs 13,2% others (p<0,05)

Cumulative incidence of AKI subgrouped by baseline serum creatine

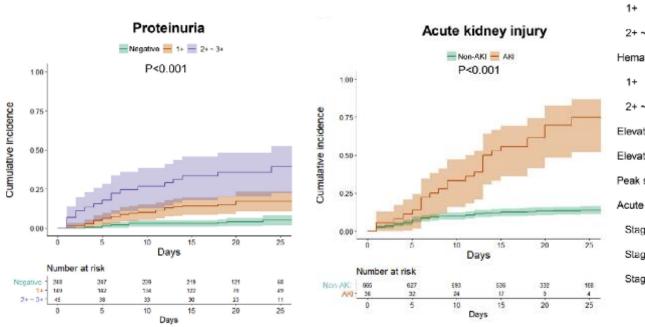

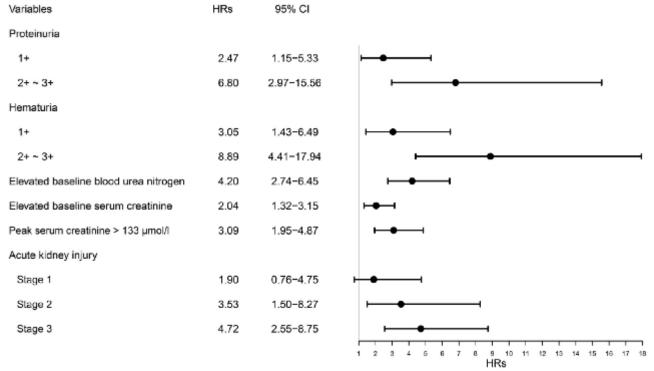

Kidney & COVID-19

Kidney abnormalities → ↑ in hospital death

After adjusting

Cumulative incidence for in-hospital death

- → High prevalence of kidney disease among hospitalized patients with COVID-19
- → Association between kidney involvement and poor outcome
- → Early detection and effective intervention of kidney involvement
- → Impact on long-term outcomes?

Neuropsychiatric disorders & COVID-19

Online network of secure rapid-response case report notification portals (CoroNerve platforms)

From April 2 to April 26, 2020 in the UK

153 unique cases (correlated with the national case identification data)

- 114 = confirmed SARS-CoV-2 infection
- 6 = probable SARS-CoV-2 infection
- 5 = possible SARS-CoV-2 infection
- 28 excluded because missing data

4 clinical syndromes associated with COVID-19

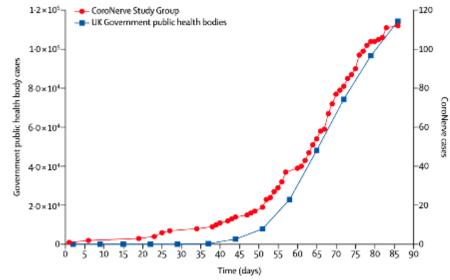

- Cerebrovascular event = 77 cases
 - Ischemic stroke / intracerebral hemorrhage
- Altered mental status = 39 cases
 - Encephalopathy /encephalitis / primary psychiatric diagnoses / ...
- **Peripheral neurology** = 6 cases
- Other neurological disorders = 3 cases

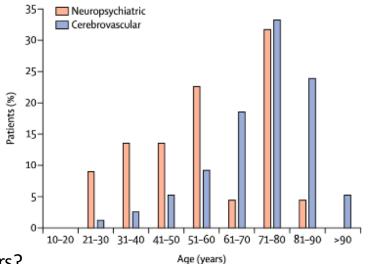

Acute alteration in mental status were overrepresented in young patients

→ Cerebrovascular events in COVID-19 → vasculopathy

→ Viral neurotropism? Host immune responses? Genetic factors?

Temporal distribution for cases notified to the CoroNerve Study group

Age distribution of patients – case definitions for cerebrovascular and neuropsychiatric events

Severity of depressive symptoms & COVID-19

Who is most at risk and how their experiences are evolving as the pandemic continues?

Explore the severity levels of depressive symptoms among individuals at high risk.

- Cohort study (COVID-19 Social Study in the UK)
- Depressive symptoms were measured on 7 occasions: the 9-item Patient Health Questionnaire (PHQ-9)
- Exposures → self-reported during the interview

Group-based trajectories of depressive symptoms were estimated using latent growth mixture (LGM) modeling.

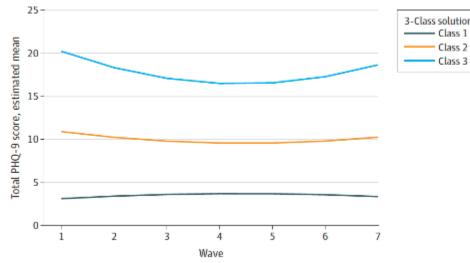

51 417 participants:

- Oldest age group > 60 y → 32,1% (higher proportion)
- Higher proportion of participants in the low and medium-income groups
- 22,1% were essential worker
- 19,9% had mental heakth condition
- 11,3% had psychological or physical abuse

→ Severe depressive symptoms decreased following the start of the lockdown but began to increase again

Characteristics of study participants (extract)

Depressive symptoms ^c	
Minimal or mild	35 715 (69.5)
Moderate	12 451 (24.2)
Severe	3251 (6.3)
Psychiatric medications, yes	7726 (18.0)

Group-Based Trajectories of Depressive Symptoms

Class 1: low depressive symptom trajectory Class 2: moderate depressive symptom trajectory Class 3: severe depressive symptom trajectory

Severity of depressive symptoms & COVID-19

Associations of Sociodemographic, Psychosocial, and Health-Related Risk Factors With the Severe Depressive Symptom Trajectories

The risk of severe depressive symptoms was higher among people:

- Experiencing abuse or low social support
- With low SEP
- With preexisting mental or physical health condition

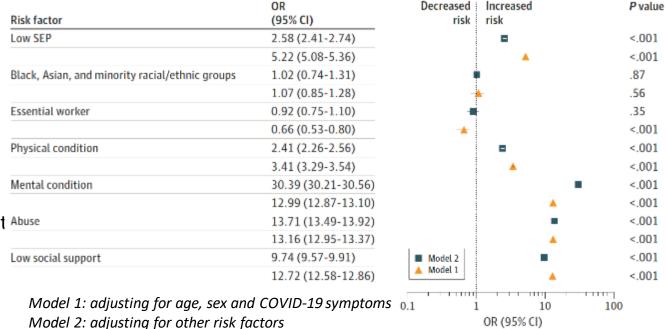

Preexisting mental health condition versus no preexisting:

Mean PHQ-9 score more than 2-fold higher

Psychological distress experienced during this pandemic may result Abuse in an increased incidence of various adverse physical health outcomes.

Limits:

- Not random sample & not nationally representative
- Self-reported measures → bias (underreported sensitive information)
- Causality cannot be assumed
- Lack data on individuals prior to lockdown

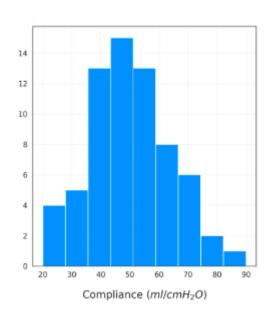

- → The odds of severe depressive symptoms were more than 5-fold higher in those facing socioeconomic disadvantage
- → Importance of developping strategies to identify at-risk person

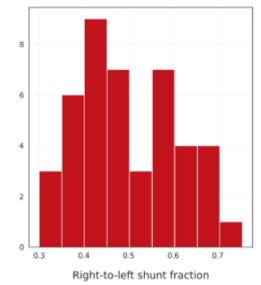

ARDS & COVID-19

- Atypical form of ARDS
- Dissociation in more than 50%:
 - Well preserved lung mechanics
 - Severity of hypoxemia

CT scan

A: spontaneous breathing

B: mechanical ventilation

Type «L»: Low elastance

- Gas volume nearly normal
 - Vt 7-8 ml/kg \rightarrow DV<14cmH₂O
- Recruitability is low
 - PEP<12cmH₂O
- Loss of hypoxic pulmonary vasoconstriction
- Ventilation/perfusion mismatch → hypoxemia
- Low lung weight → ground glass densities

Type «H»: High elastance (10 – 30%)

Evolution of the COVID-19 injury attributable to P-SILI

- Increase oedema → decrease gas volume
 - Vt = 6ml/kg → DV<14cmH₂O
- Recruitability is high
 - PEP>12cmH₂O (carefully)
- High lung weight → bilateral condensations
 - Prone position

Antihypertensive drugs & COVID-19

- Observational study
- Lombardy Region in Italy data extracted from the registry
- February 21 to March 11
- Patient older than 40 years
- 6272 cases matched to 30759 controls (on age, sex & municipality residence)
- Use of antihypertensive drugs
 - ARBs 22,2% among cases and 19,2% among controls
 - ACE inhibitors 23,9% among cases and 21,4% among controls
- Neither ARBs nor ACE inhibitors had a significant association with risk of COVID-19
 - Risk similar for women and men
 - Not modified by age severity of clinical manifestation course of COVID-19
 - No evidence of an independent relationship between RAAS blockers and the susceptibility to COVID-19

Variable	Odds Ratio for Co	Odds Ratio for Covid-19 (95% CI)*		
	Unadjusted	Adjusted		
No use during 2019	1.00 (reference)	1.00 (reference		
Use only as monotherapy	1.39 (1.28-1.51)	1.03 (0.90-1.18		
Use as combination therapy	1.60 (1.50-1.72)	0.99 (0.90–1.09		

^{*} Shown are odds ratios for Covid-19 associated with drug use. Nonuse was considered as the reference. Estimates were obtained by fitting conditional logistic-regression models. Both unadjusted estimates and estimates that were fully adjusted for drugs and coexisting conditions are shown.

Limits

- Change in strategy to test for coronavirus during study
- Information on drug use is limited to prescription
- Exposure to antihypertensive drug not available after December 2019
- Control group included persons with COVID-19
- Unmeasured confounders

Antihypertensive drugs & COVID-19

- Observational study
- New-York University Use of the NYU Langone Health
- March 1 to April 15, 2020
- All patients with Covid-19 test results recorded
- Extracted from the chart (preceding 18 months)
 - Medical history
 - Medication data
- For a given medication, used a propensity-score models that adjusted for multiple variable
- 12594 patients
 - o 5894 COVID-19+
 - 4357 history of hypertension → 2573 COVID-19+
- No association with any medication studied of
 - Risk of severe COVID-19
 - Increased likelihood of a positive test

Medication	Matched Patients with Hypertension			All Matched Patients			
	Severe Covid-19 in Patients Treated with Medication	Severe Covid-19 in Patients Not Treated with Medication	Median Difference (95% CI)	Severe Covid-19 in Patients Treated with Medication	Severe Covid-19 in Patients Not Treated with Medication	Median Difference (95% CI)	
	no./tatal no. (%)		percentage points no./tatal no		ital no. (%)	no. (%) percentage points	
ACE inhibitor	139/584 (23.8)	158/583 (27.1)	-3.3 (-8.2 to 1.7)	150/627 (23.9)	169/653 (25.9)	-1.9 (-6.6 to 2.8)	
ARB	161/629 (25.6)	156/612 (25.5)	0.1 (-4.8 to 4.9)	162/664 (24.4)	165/639 (25.8)	-1.4 (-6.1 to 3.3)	
ACE inhibitor or ARB	252/1019 (24.7)	249/986 (25.3)	-0.5 (-4.3 to 3.2)	275/1110 (24.8)	274/1101 (24.9)	-0.1 (-3.7 to 3.5)	
Beta-blocker	210/792 (26.5)	231/829 (27.9)	-1.4 (-5.7 to 3.0)	230/912 (25.2)	250/976 (25.6)	-0.4 (-4.3 to 3.6)	
Calcium-channel blocker	253/950 (26.6)	207/930 (22.3)	4.4 (0.5 to 8.2)	263/992 (26.5)	235/976 (24.1)	2.4 (-1.4 to 6.2)	
Thiazide diuretic	116/515 (22.5)	114/520 (21.9)	0.6 (-4.5 to 5.7)	120/549 (21.9)	149/590 (25.3)	-3.4 (-8.3 to 1.6)	

Limits

- Variation in the diagnostic characteristic for the COVID-19 testing method
- Multiple tests for some patients
- Some patients may have been tested at other heath systems
- May not reflect actual drug exposure
- Not account for socioeconomic status, insurance, ...
- Additional unmeasured confounders

→ Rule out that the risk was higher among treated patients than among untreated patients

Risk factors of mortality

The proportion of hospitalized and fatal SARS-CoV-2 cases per 100 000 individuals relative to the total Danish population within each age group

Hospitalized test-positive cases

Nationwide cohort of all Danish individuals tested for SARS-CoV-2 The study cohort was linked to the Danish administrative and health registrie

11 122 cases with PCR positive: 80% were community-managed & 20% were hospitalized (whereas 2,8% in an ICU)

30 days all cause of mortality = 5,2%

Risk factors of death:

Sex:

• adjusted for age and number of co-morbidities, ORs = $2,1;Cl_{95\%}$ [1.7–2.6] for men

Age:

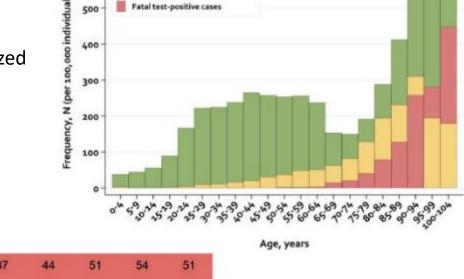

- 70 79 years: OR= 15; Cl_{95%} [9– 26]
- 80-89 years: OR= 30; Cl_{95%} [17–52]
- >90 years: OR= 90; Cl_{95%} [50–162]

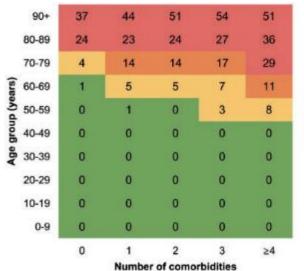

Number of co-morbidities:

- OR=5.2; $CI_{95\%}$ [3.4–8.0], for cases with at least four co-morbidities
- 79% of deaths had at least two co-morbidities

Chronic diseases:

- Ischemic heart disease & hypertension → ORs 1,1 to 1,3
- Organ transplantation → OR 3,4

Proportion of patients dying among SARS-CoV-2 PCR-positive cases within different subgroups of age and number of comorbidities

2549 children in USA

Age (median): 11 years [0 – 17]

• Male: 57 %

Exposure to a COVID-19 patients:
 91% (household / community)

• Symptoms (on 291 cases)

• Fever: 56%

• Cough: 54%

• Dyspnea: 13%

Diarrhea: 13%

Nausea/vomiting: 11%

Abdominal pain: 5,8%

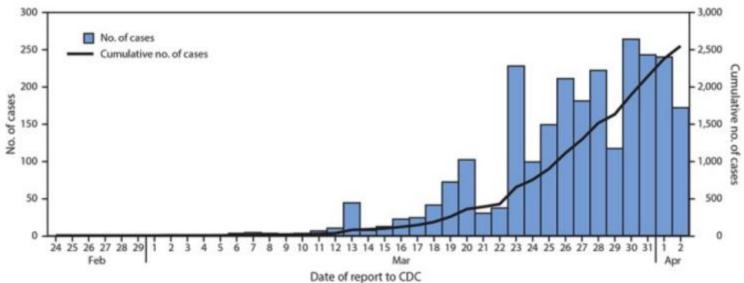

• ...

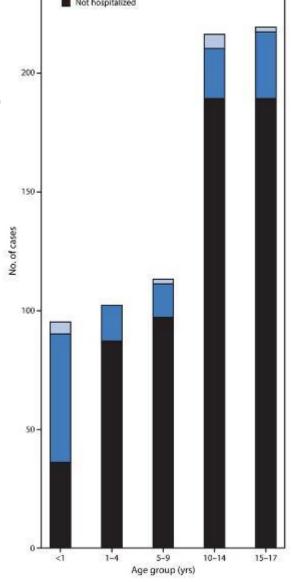

• Hospitalized: 147

• ICU admission: 15

• Case fatality rate: 0,1%

Children aged <18 years, by date reported to CDC

Hospitalized

Pediatric inflammatory multisystem syndrome

Observation of a large number of children hospitalized for cardiogenic shock potentially associated with SARS-CoV-2

- Retrospective cohort 2 countries (France & Switzerland) 14 centers
- 35 children Age (median): 10 years [2 16] 51% were male
- 88% were positive for SARS-CoV-2 (nasopharyngeal swabs or serology)

Evolution

- 71% had total recovery left ventricular ejection fraction at day 7
- Time to full recovery = 2 days [2 5]

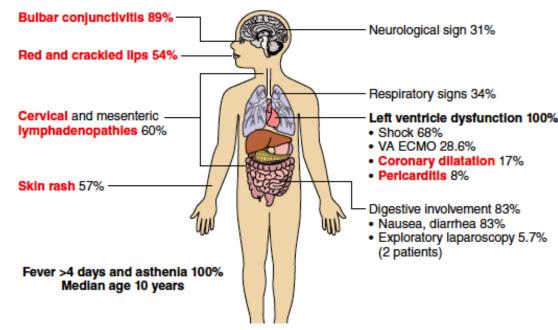

<u>Treatment</u> (no recommendation for the moment)

- 62% had invasive respiratory support
- 28% needed VA-ECMO

New disease related to SARS-CoV-2? No precise arguments Shares some similarities with KD

→ Understanding the immune mechanisms of this disease is a priority

SARS-COV-2 related multisystem inflammation

Differences with Kawasaki disease

- Older (median age: 8 to 10y)
- Incomplete forms of KD
- Limited number of coronary artery dilatation

Pediatric inflammatory multisystem syndrome

Cohort of patients with KD in Paris region associated with SARS-CoV-2 (\rightarrow 16 patients)

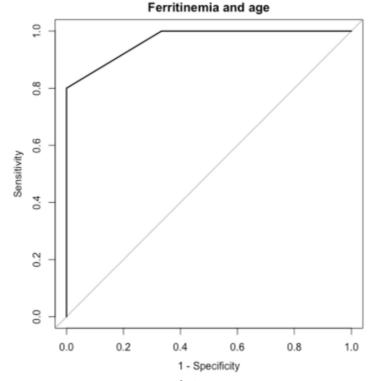

Compared with a historical cohort of «classical KD» (\rightarrow 220 patients)

Cohort of Kawa-COVID-19

- Median age = 10 y IQR [4,7 12,5]
- Median time from the onset of KD to hospitalization was 5 days
- RT PCR all site positive: 69% (11 cases)
- Cardiac ultrasound was abnormal in 11 patients
- No death all are in remission.

Kawa-COVID-19 versus historical cohort

- Older 10 vs 2 years (p<0,0001)
- Lower platelet count (p<0,0001)
- Lower lymphocyte counts (p<0,0001)
- Higher frequency of cardiac involvement: myocarditis & pericarditis

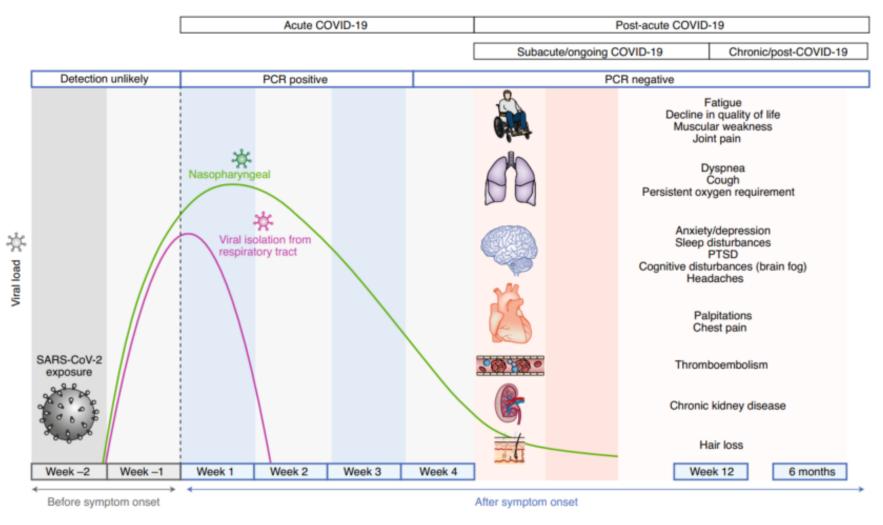

ROC curve of the severity score

Factor prognostic for the development of severe disease

- Age > 5 years
- Ferritinaemia >1400 μg/L

Timeline of post-acute COVID-19. Acute COVID-19 usually lasts until 4 weeks from symptom onset, beyond which replication-competent SARS-CoV-2 has not been isolated. Post-acute COVID-19 is defined as persistent symptoms and/or delayed or long-term complications beyond 4 weeks from the onset of symptoms. The common symptoms observed in post-acute COVID-19 are summarized.

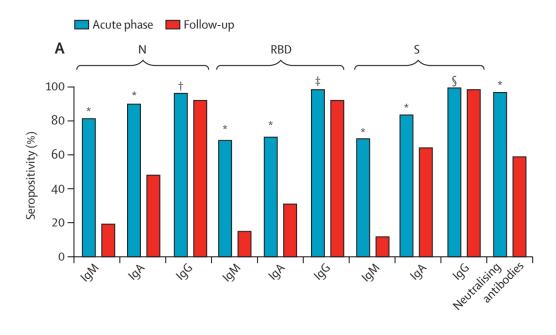

Cohort of adult Covid-19 patients hospitalized between Jan and May 2020, Wuhan (China), 1733 patients enrolled – 6 month follow-up

	Total	Scale 3 (no supplemental oxygen)	Scale 4 (supplemental oxygen)	Scale 5-6 (HFNC, NIV or IMV)
At least one symptom	1265/1655 (76%)	344/424 (81%)	820/1114 (74%)	101/117 (86%)
mMRC score	1196/1615 (74%)	323/425 (76%)	802/1079 (74%)	71/111 (64%)
Pain or discomfort (EQ-5D-5L questionnaire)	431/1616 (27%)	111/422 (26%)	274/1082 (25%)	46/112 (41%)
Anxiety or depression (EQ-5D-5L questionnaire)	367/1617 (23%)	98/425 (23%)	233/1081 (22%)	36/111 (32%)
Quality of life (0-100)	367/1617 (23%)	98/425 (23%)	233/1081 (22%)	36/111 (32%)
Distance walked in 6 min – lower than normal range	392/1692 (23%)	103/423 (24%)	255/1153 (22%)	34/116 (29%)
eGFR <90 mL/min per 1.73m²	487/1393 (35%)	121/338 (36%)	326/967 (34%)	40/88 (45%)
Chest CT – at least one abnormal pattern		49 (52%)	87/161 (54%)	50/92 (54%)

- Most common symptoms were fatigue or muscle weakness (63% of total) and sleep difficulties (26% of total)
- > Pulmonary diffusion abnormality were common, risk of anxiety or depression and impaired pulmonary diffusion capacities were higher in patients with more severe illness
 - The seropositivity and titres of the neutralising antibodies were significantly lower than at acute phase.

Cohort of adult Covid-19 patients hospitalized between Mar and Jun 2020, Italy, 238 patients enrolled – **4 month follow-up** (27.7% no oxygen required; 20.6% noninvasive ventilation; 8.8% mechanical ventilation; 11.8% ICU)

Covid-19 symptoms

	Acute phase	At follow-up	
Fever	215 (90.3%)	0	
Cough	132 (55.5%)	6 (2.5%)	
Dyspnea	129 (54.2%)	13 (5.5%)	
Ageusia	70 (29.4%)	12 (5.0%)	
Anosmia	63 (26.5%)	11 (4.6%)	
Diarrhea	54 (22.7%)	3 (1.3%)	
Arthralgia	46 (19.3%)	14 (5.9%)	
Myalgia	45 (18.9%)	14 (5.9%)	
Chest pain	2 (0.8%)	1 (0.4%)	
Sore throat	1 (0.4%)	0	
Headache	1 (0.4%)	0	

Pulmonary Function Testing

- D_{LCO} <80% in 51.6% of 219 tested patients</p>
 - Risk factors associated (OR[95% CI]) included chronic kidney disease (10.12[2.00-51.05]) and female sex (4.33[2.25-8.33]) and modality of oxygen delivery (2.20[0.57-8.48])
- \triangleright D_{LCO} <60% in 15.5% of patients
 - Risk factors associated (OR[95% CI]) included ICU admission (5.76[1.37-24.25]), COPD (5.52[1.37-23.08]) and chronic kidney disease (4.75[1.19-19.00])

Physical Performance Evaluation

- A total of 52.8% patients had functional impairement
 - 22.3 patients had limited mobility based on SPPB test
 - 31.5% of all other patients had subtler impairement in 2-min walking test

Posttraumatic syndrome signs

According to IES-R questionnaire results:

- > 25.6% had mild PTS symptoms
- ➤ 11.3% had moderate PTS symptoms
- > 5.9% had severe PTS symptoms

Limitations:

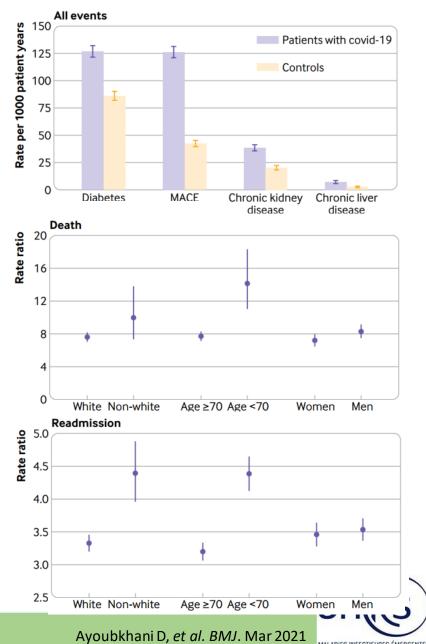

- Previously hospitalised patients only
- Potential selection bias patients who declined study participation may have perceived full recovery

47 780 individuals (mean age 65, 55% men) hospitalised with covid-19 and discharged alive by 31 August 2020, exactly matched to controls from a pool of ~50 million people in England for personal and clinical characteristics.

- Admission to hospital for covid-19 was associated with an increased risk of readmission (3.5 times greater) and death (7.7 times greater) after discharge, compared to matched control.
- ➤ Rates of multiorgan dysfunction after discharge were higher in the Covid-19 cohort as compared to controls (Respiratory diseases 29% of individuals [27.3 times greater for new onset diagnoses], diabetes 4.0% [3.0], MAjor Cardiovascular Events 4.8% [2.8], chronic kidney disease 1.5% [1.9], chronic liver disease 0.3% [1.5]).
- ➤ Absolute risk of death, readmission, multiorgan dysfunction after discharge was greater in individuals ≥70 and of white ethnic background.
- Secondary analysis showed that individuals discharged from ICU after covid-19 experienced greater rates of death and readmission than those not admitted to ICUs.

CLINIC & PHYSIOPATHOLOGY (April 2021)

1. What are the mechanisms of action of SARS-CoV-2?

- It uses ACE2 receptor to enter the cell and can produce a hyper-inflammatory response
- Activation of innate and adaptative immune pathways
- Auto-Abs against type I IFNs are a cause of severe SARS-CoV-2 infection

1. What are the cellular and humoral host responses against SARS-CoV-2 infection?

- Induces long lasting T and B cell immunity against the Spike protein and the structural N protein
- Recovered from mild COVID-19 → robust antibody response to spike protein
- Most symptomatic and asymptomatic patients present strong IgM and IgG responses, the latter lasting up to 6 months
- Anti-spike protein antibody titers appear to correlate with viral neutralization for several months

2. What is the clinical presentation of COVID-19 in adults and children?

- Most persons are asymptomatic or mildly symptomatic
- Independent risk factors of mortality: age obesity chronic disease
- Children are less represented than adults and have less severe or critical forms of the disease

3. Is there multiple-organ damage?

- Predominantly lung damage → prognostic of the disease
- Several cases of heart & kidney damage

4. What are the long term effects of Covid-19 (Long Covid)?

- Long term effects include fatigue, pulmonary function impairment and psychological sequelae up to 6 months after infection
- ICU admission for Covid-19 is associated to increased risks of readmission and death
